Abstract

Introduction: Primary acute angle closure glaucoma (PAACG) is an ophthalmic emergency and potentially blinding diseases (the distribution of ACG has shown striking differences by racial groups in individual over 40 years of age with optic nerve damage which occurs after a sudden rise of intraocular pressure associated with a PAACG episodes).

Materials and Methods: The study enrolled 30 patients with unilateral PAACG attack in the first 4 months after remission and 30 normal persons for control. Using the stratus optical coherence tomography (OCT) (Version 4.0.2) and GDx variable corneal compensation (VCC), the retinal nerve fiber layer (RNFL) thickness was assessed in both eyes within 2 weeks after PAACG and again after 4 months. As assessed by OCT and GDx VCC, RNFL thickness in subjects became thicker at 2 weeks and thinner by 4 months of acute attack compared with the fellow unaffected and normal eyes.

Results: RNFL of PAACG eyes became thicker by an average of 143.87 ± 15.23 µm compared to 108.53 ± 7.44 µm in the fellow eye and 108.90 ± 7.93 µm in the normal eye (P < 0.001) within 2 weeks. It became thinner by an average of 88.73 ± 10.27 µm in the affected eyes compared to 107.87 ± 7.20 µm in the fellow eyes and 107.17 ± 7.29 µm in the normal eye (P < 0.001) at 4 months. Significant differences were demonstrated comparing the average and four quadrant RNFL thickness for attacked eyes and those of normal control (P < 0.001) and fellow eyes (P < 0.001-0.002) using analysis of variance both within 2 weeks and at 4 months after remission.

Conclusion: Using OCT and GDx VCC, RNFL thickness was found increased in eyes immediately after an episode of PAACG followed by a decrease in RNFL thickness over time (up to 4 months). This detection can aid in better understanding of the pathological changes in the retina in PAACG and thus help in the assessment and management of these patients.

INTRODUCTION

Primary acute angle closure glaucoma (PAACG) is an ophthalmic emergency and potentially blinding diseases (the distribution of ACG has shown striking differences by racial groups in individual over 40 years of age, with optic nerve damage which occurs after a sudden rise of intraocular pressure [IOP] associated with a PAACG episodes). The optic disc appears edematous during this episode and pallor with or without cupping may develop after remission. When treatment is delayed vision may reduce markedly to hand movement or light perception.¹ Pathologically, the ganglion cells die by apoptosis and their axons disappear over and above the normal apoptotic loss that occurs naturally with age. Perimetric examination during acute episodes is difficult and usually...
unreliable. After remission, visual field defect varies greatly in severity and type. Measurement of retinal nerve fiber layer (RNFL) thickness loss after PAACG is very important as it is both objective and sensitive in terms of detection of optic disc damage with either normal or unreliable fields.

In recent years various glaucoma imaging modalities - optical coherence tomography (OCT), scanning laser polarimetry (SLP), confocal scanning laser ophthalmoscopy, SLP + variable corneal compensation (VCC) (GDx VCC, Carl Zeiss Meditec, Inc, Dublin, CA) in the management of glaucoma. OCT is a high-resolution glaucoma imaging device capable of obtaining reproducible RNFL thickness measurement. This device has been shown in cross-sectional studies to allow differentiation between normal and glaucoma patient. Studies have shown that SLP with VCC significantly improves the structure - function relationship agreement with other imaging technologies and discriminating power for detection for glaucoma.

MATERIALS AND METHODS

This was a prospective observational study undertaken in a tertiary health-care center in West Bengal from March 2014 to February 2015 which was approved by institution ethics committee. A prior written consent from the participants was taken. The study population included 30 eyes of the patient with unilateral attack of PAACG, 30 fellow eyes and 30 eyes of control, patient attending ophthalmology outpatient department of same age and sex without symptoms and sign suggestive of ACG over a time period of 1 year. To be eligible patients required to have at least two of the following symptoms - ocular pain, blurred vision, headache, vomiting and presence of any of the signs like conjunctival congestion, mid dilated nonreactive pupil, corneal edema, IOP ≥45 mmHg, closed angle on gonioscopy, duration of PAACG attack ≤120 h and complete resolution of attack with medical therapy and surgery and IOP below 21 mm Hg after treatment. Patients were excluded if the attack was bilateral, secondary angle closure, PAACG of the fellow eye in the past, refractive error of ≥5.00 D spherical and or 3.0 D cylindrical, persistent corneal edema or opacity after PAACG attack, previous intraocular surgery or intraocular disease that may result in abnormal RNFL thickness. OCT and GDx VCC were done once at 2 weeks and an interval of 4 months. The parameters studied were the global RNFL thickness and four quadrant RNFL thickness. Each subject underwent a comprehensive ophthalmological examination including best corrected visual acuity, IOP by Goldmann applanation tonometry, Slitlamp Biomicroscopy, Gonioscopy, Fundus evaluation on slit lamp with +90 D lens, standard achromatic perimetry on Humphrey Field Analyzer using 30-2 testing protocol by Swedish interactive threshold algorithm standard protocol. P < 0.05 was considered as significant.

RESULTS

A total of 30 patients and 30 controls with the same sex ratio with age group between 25 and 65 years were studied (Table 1). The mean duration of the PAACG attack was 72 ± 48 h. The global and four quadrant RNFL thickness as measured by OCT and GDx VCC showed a statistically significant difference between the eyes with acute attack and fellow or normal eye (P < 0.001) at 2 weeks - Table 2. These parameters also changed significantly within 4 months in eyes suffering from the acute attack. The statistical analysis was done by one-way analysis of variance. The average and (four quadrants) RNFL thickness in the eyes suffering from PAACG attack increased to 143.87±15.23 µ compared to 108.53±7.44 µ of the unaffected fellow eyes at 2 weeks (P < 0.001). The four quadrants RNFL also increased in the affected eyes at 2 weeks but not in the fellow eyes. At 4 months of follow-up also the four quadrant RNFL thickness decreased in the affected eye compared to the fellow eyes or normal eyes (P < 0.001).

RNFL: Retinal nerve fiber layer, OCT: Optical coherence tomography, SD: Standard deviation, VCC: Variable corneal compensation
provide Table 2. Therefore, we conclude that there is an initial increased in global RNFL thickness after an acute attack followed by a decrease around 4 months.

The average, temporal, superior, nasal and inferior peripapillary RNFL thickness as measured by OCT and GDx showed a statistically significant difference between the eyes with acute attack and fellow or normal eyes, respectively ($P < 0.001$).

**DISCUSSION**

In our study, the possible explanation for the increased global average and four quadrant RNFL thicknesses at 2 weeks is the apparent edema of the Optic Nerve Head (ONH) after a PAACG attack persisting up to 2 weeks after onset in spite of remission. Tso and Fine also found from histopathology that the peripapillary RNFL thickness increased in patient with optic disc edema. Yoles and Schwartz have suggested a mechanism whereby glaucomatos neuropathy continues to progress even after alleviation of the high IOP.

In this study, we find that the RNFL thickness in the affected eyes correlates with the interval of follow-up of PAACG. We find that there is a rapid thinning of RNFL and gradual stabilization thereafter. This suggests that a longitudinal follow-up to detect changes in RNFL thickness is not only necessary to assess the actual loss and damage but also provides more information. The average and four quadrant RNFL thicknesses after the acute attack decreased in the affected eyes but not in the fellow eyes during the 4-month follow-up and an average and four quadrants RNFL thickness for the affected eyes correlated strongly with interval of follow-up, according to inverse regression analysis in this study.

The main limitation of the study was a relatively small sample size and limited number of the patient with less severe PAACG episodes (<48 h).

**CONCLUSION**

Results of this intereye and intertest comparison of RNFL thickness after a single unilateral PAACG attack using Stratus OCT and GDx VCC demonstrated an initial increase in diffuse RNFL thickness followed by a decrease. The interval between the episodes and measurement influences the result of RNFL thickness assessment. It thus appears reasonable to suggest that longitudinal follow-up must be considered in any comprehensive study of the long-term effect of PAACG.
