Abstract

Introduction: Pterygium excision surgery poses distinct problem like high post-operative recurrence. Many surgical approaches have been tried to decrease recurrences. Currently, intraoperative Mitomycin C (MMC) application is used as adjunct apart from the standard limbal-conjunctival autograft.

Purpose: To study the efficiency and MMC related complications when MMC was applied on the under surface of the conjunctiva of dissected pterygium.

Materials and Methods: This is a non-comparing prospective interventional case series of 38 patients. The patients underwent standard pterygium excision with intraoperative MMC application on the under surface of dissected pterygium conjunctiva and followed for 1-year.

Result: Out of 38 patients no one had a recurrence of pterygium. Only one patient has post-operative increased corneal astigmatism (P > 0.05).

Conclusion: Intraoperative application of MMC in the strength of 0.2 mg/ml for 90 s is effective in preventing the recurrence of pterygium without any post-operative major complication.

Key words: Astigmatism, Conjunctiva, Mitomycin C, Recurrent pterygium, Streptomyces

INTRODUCTION

Pterygium is a common ocular disorder treated by surgical excision. It is more prevalent in the equatorial region. Ultraviolet B-ray is the most important environmental factor. P53 and human papilloma virus and deficiency of limbal stem cell may be other factors causing pterygium. They may cause gene mutation resulting in abnormal expression of the conjunctival epithelium.

One of the major problems with pterygium surgery is a high rate of recurrence. It ranges from 30% to 89%. Various methods have been developed to tackle this problem. Intraoperative or post-operative use of Mitomycin C (MMC) is one of the adjunctive treatments that can significantly reduce the rate of recurrence. MMC is an antibiotic isolated from Streptomyces caespitosus. It is an alkylating agent. Pathological changes in pterygium occur in conjunctival epithelium.

The aim of this study was to evaluate efficacy and MMC related complications when MMC was applied on the under surface of conjunctiva of dissected pterygium.

MATERIALS AND METHODS

The study is a prospective non-comparative interventional case series. A total of 38 consecutive patients were included through the period of 3 years. Patients with dry eye, inflamed eye, and immune disorder were excluded. After taking informed consent patients under went
standard pterygium excision. Overlying conjunctiva was separated from underlying tissue and flesh of the pterygium was excised. Tip of the conjunctiva was sacrificed. Intraoperative MMC of 0.2 mg/ml strength for 90 s was applied on the under surface of dissected pterygium conjunctiva while protecting the sclera from MMC exposure by the use of spatula over the sclera during MMC application (Figure 1). Then, it was washed thoroughly. Freely mobile conjunctiva was anchored. The patients were followed up on 1st week, 4th week, 3rd month and after 1-year. Patients were looked for bleaching, thinning, dellen, ulceration, persistent epithelial defect, visual acuity, and recurrence. Recurrence was defined as fibrotic vascularization tissue crossing through the limbus.

RESULT

An average duration of surgery was 13 min. Pre-operative best-corrected vision was <6/60 in 22 patients and better than 6/36 in 16 patients. 26 patients had a cataract. Age ranged from 22 to 69 years. Male-female ratio was 3:1. No epithelial defect was present by the 7th day. No case of dellen, thinning, ulceration or ble-aching was seen. Visual acuity increased in all the patients after surgery with a decrease in astigmatism. Astigmatism increased in one eye of a patient who was operated for recurrence of pterygium in his both the eyes after 3 months.

DISCUSSION

The recurrence rate for bare sclera excision alone is unacceptably high, 30-80%. Singh et al. introduced the use of MMC as an adjunct to pterygium surgery to ophthalmology in 1988. Although MMC significantly reduced the rate of recurrence to a range of <10%, severe complications such as ocular surface disorder, corneal perforation, scleral calcification, corectopia, iritis, cataract, photophobia, pain and glaucoma were reported by Singh et al. These complications were mostly related to uncontrolled use of high and cumulative dose of MMC and its application over sclera. Despite the fact that early complications can be avoided and controlled, one cannot implicate the outcome of MMC application years after its use (remember beta radiation). The recurrence rate in conjunctival autograft varied from 2% to 39% which is comparable to MMC use. Inter surgeon variation contributed to recurrence rate reported in conjunctival and amniotic membrane graft. We applied MMC on the under surface of conjunctiva while protecting the sclera from MMC exposure assuming that we should target proliferating subconjunctival tissue rather than innocent sclera. All the recurrences occur during the first 6 months of surgery when MMC is not applied. MMC is effective even if applied 0.2 mg/ml for 30 s. Based on this, we applied MMC in the strength of 0.2 mg/ml for 90 s.

In our study, no recurrence was seen during 36 months of follow-up. No complications related to MMC use were seen. Average surgical time was only 13 min in this study. Visual acuity increased in all cases following pterygium surgery due to decreased astigmatism. 26 patients underwent cataract surgery 4 weeks after pterygium surgery. There was an increase in astigmatism in one eye of case number one 2 weeks after pterygium excision, may be due to increase in fibrosis but remained stable in following visits. The technique is fast and simple, while conjunctival or amniotic membrane graft is not only time consuming but requires special skill.

CONCLUSION

Application of MMC in the strength of 0.2 mg/ml for 90 s is effective in preventing the recurrence and causes no harm to the vital parts of the eye.
