Abstract

Scrotal calcinosis is a rare benign disorder involving scrotal skin resulting from deposition of calcium within the dermis. It was first described by Lewinskey in 1883. Deposition of calcium in the skin, subcutaneous tissue, muscles, and visceral organs is known as calcinosis and it more commonly involves skin and it is called calcinosis cutis. There are four types of calcinosis cutis based on their etiology such as dystrophic, metastatic, iatrogenic, and idiopathic.¹ Age group is 20-40 years.¹⁻⁴ Various theories on pathogenesis have been proposed by authors favoring idiopathic and dystrophic calcification. In dystrophic calcification, calcification occurs as a consequence of pre-existing condition such as an epidermal cyst, etc. and when there is no evidence of pre-existing pathology it is termed as idiopathic scrotal calcinosis. Metastatic calcifications are usually generalized and due to metabolic changes such as hypercalcemia and hyperphosphatemia as in end-stage renal diseases and hyperparathyroidism and dermatomyositis.⁷,⁸ Pabuccuogh et al. proposed degeneration and necrosis of dartos muscle as the reason for calcification which is supported by King et al., Fischer et al., Armjio et al., and Kelten et al.⁷ Ito et al. described scrotal calcinosis is consequence of excessive discharge and accumulation of material debris in lumina of eccrine epithelial cyst using immunohistochemistry which showed slight positivity for antibodies to sulfated mucopolysaccharides.⁴ Shapiro et al. 14 case series proposed scrotal calcinosis is idiopathic as there is no epithelial lining around calcium deposition, keratin remnants, granulomatous reaction and, inflammation infiltrates which is supported by Shal et al., Parlakgumus et al., Anureet et al., Wright et al., Karaca et al., and Dombale et al.⁵,⁶,⁸ Fukaya et al. and Ueds et al. mentioned role of mast cell in formation of calcification.⁷ Dini et al. proposed the term “idiopathic” can be used if the cause is not known as in our case. In our case, we are reporting a case of idiopathic scrotal calcinosis evidenced by the lack of inflammatory and
epithelial cells. In this article, we have also elaborated the available literature on scrotal calcinosis.

**CASE REPORT**

A 45-year-old diabetic male patient presented with painless multiple swelling in the scrotum for 8 years which gradually progressed over the years. He neither gave any history suggestive of metabolic disorder, hormonal derangement, sexually transmitted diseases, nor trauma. On examination, multiple yellowish, firm nodules present in the scrotal skin with no ulceration or discharge. (Figure 1) The patient’s blood picture, blood sugar, serum calcium, phosphate, parathyroid hormone, calcitonin, and vitamin D levels are within normal limits. (Figure 2) Excision of the nodules from the scrotal skin was done. Grossly excised specimen is about 4 cm × 3 cm × 2 cm and chalky white areas were seen below the skin on cut section. (Figure 3) Microscopic picture shows epidermis and dermis with multiple foci of calcium deposits in the subcutaneous tissue with no malignancy or inflammatory cells seen. (Figure 4)

**DISCUSSION**

Idiopathic scrotal calcinosis is a rare benign condition with painless slow-growing nodular masses within the dermis of the scrotal skin. Incidence of the disease is not known. It was first described by Lewinskey in 1883. Deposition of calcium in the skin, subcutaneous tissue, muscles, and visceral organs is known as calcinosis, and it more commonly involves skin and is called calcinosis cutis. There are four types of calcinosis cutis based on their etiology such as dystrophic, metastatic, iatrogenic, and idiopathic.

Scrotal calcinosis is usually asymptomatic but occasionally causes heaviness, itching, ulceration, and chalky white
exudative discharge.2,5,6,8 The patient mainly comes for cosmetic reasons.8 Age group is 20-40 years, youngest and oldest reported are 9 and 85 years, respectively.2,5,6 Initially, it resembles the color of scrotal skin later it changes into yellow, and duration is about 10 years ranging from 3 months to 46 years.8

Microscopic picture shows amorphous basophilic calcium deposits within dermis surrounded by lymphocytic infiltration, histiocytes, and hyalinization.2,5,6 Histological picture shows muscle, epithelial cells, and foreign body granuloma during early stage and it shows only calcification in the advanced stage.2

The pathogenesis is still in the debate, various theories have been proposed by authors favoring idiopathic and dystrophic calcification. In dystrophic calcification, there must be a local favoring condition such as pre-existing epidermal cyst, eccrine duct milia, eccrine epithelial cyst, degenerated dartos muscle, and connective tissue disorders such as scleroderma, systemic lupus erythematosus, dermatomyositis, and minor trauma. Squamous cell epithelial lining may present, and patient has normal serum calcium and phosphorus levels.1

Song et al. described spectrum of changes takes place in scrotal calcinosis as mild to moderate inflammation of epidermal cyst is followed by mononuclear cell infiltration and foreign body granuloma formation and lastly resorption of cyst wall and keratin remnants leaving calcium deposits only6 which is supported by Swinhart et al., Akosa et al., Saad et al., Dubey et al., Parlakgumus et al., and Dini and Colatranesi et al.2,6,8

Pabuccuoglu et al. proposed degeneration and necrosis of dartos muscle as the reason for calcification which is supported by King et al., Fischer et al., Armjo et al., and Kelten et al.7 Ito et al. described scrotal calcinosis is consequence of excessive discharge and accumulation of material debris in lumina of eccrine epithelial cyst using immunohistochemistry which showed slight positivity for antibodies to sulfated mucopolysaccharides.4

Dare and Axelson et al. supported scrotal calcinosis arising from pre-existing eccrine milia using immunohistochemistry which showed antibodies to carcinoembryonic antigen.6 Carson et al. described sequences following minor trauma and invasion of nanobacteria and formation of calcium apatite crystals.9 Veress and Feinstein et al. favored minor trauma following which calcification occur.10

Metastatic calcifications are usually generalized and due to metabolic changes such as hypercalcemia and hyperphosphatemia as in end-stage renal diseases hyperparathyroidism and dermatomyositis involving visceral organs and joints.5,11,12 Pallavi et al. reported as case of scrotal calcinosis due to normocalcemic hyperparathyroidism which doesn’t need parathyroidectomy unless symptomatic.11

Shapiro et al. 14 case series proposed scrotal calcinosis is idiopathic as there is no epithelial lining around calcium deposition, keratin remnants, granulomatous reaction, and inflammation infiltrates which is supported by Shal et al., Parlakgumus et al., Anureet et al., Wright et al., Karaca et al., and Dombale et al.2,3,8 Fukaya et al. and Ueds et al. mentioned role of mast cell in formation of calcification.7,9

Dini et al. proposed the term “idiopathic” can be used if the cause is not known7 as in our case. Idiopathic and dystrophic calcifications are usually involves one general area (calcinosis circumscripta). The iatrogenic calcifications mainly occur at the site of invasive procedure due to tissue damage.12

Differential diagnosis are teratoma, gonadoblastomas, Leydig cell tumors, calcified onchocercoma, neurofibroma, ancient schwannomas, steatomas, lipomas, fibromas, and scrotal calcinosis may also be due to chronic epididymitis, calcified appendix testis, appendix epididymis, and sperm granuloma due to sperm extravasation and hematoma.4,8

Diagnosis is confirmed by biopsy. If swelling is 4 mm, pinch and punch excision is advised.8 Surgery is the treatment of choice.4,8 If it is massive, subtotal excision of the scrotal wall is preferred. If it is extensively involved, excision followed by complex scrotal reconstruction using meshed split thickness skin graft as the scrotal skin is rugged.8 Recurrence is very low mainly due to microscopic foci of calcification left over.8

CONCLUSION

Idiopathic scrotal calcinosis cutis is a rare benign lesion. Metabolic and hormonal work-up is required to rule out other causes. Irrespective of the etiology, surgical excision is required both for confirming the diagnosis as well as for treatment. Scrotal calcinosis must be included in the differential diagnosis of cutaneous swellings in the scrotal region.
