Abstract

Introduction: Obesity is the most prevalent form of nutritional disorder in many of the affluent countries. Obesity is a state of excess adipose tissue mass.

Materials and Methods: Secondary data analysis of a school-based cross-sectional study in a rural and urban school of Kochi city. Weight, height, sex, and age routinely recorded by health visitors. Height, weight, and body mass index (BMI) standardized for age and sex. SD score >1.04 for BMI (>85th centile) was defined as overweight and >1.64 (>95th centile) as obese.

Results: Out of the 254 girls of the rural school, 6 were obese (8.74%) and 25 were overweight (42.66%). Of these, obesity and overweight were more common among 12-year-old girls, 6.06% and 12.12%, respectively. Of the 220 girls of urban schools, 6 were obese (11.08%) and 21 were overweight (49.9%). Of these, obesity and overweight were more common in the 13 years old age group of 3 (5.56%) and 8 (14.81%), respectively. Of the 191 boys of the rural school, only 1 (1.27%) was obese and 12 (29.13%) was overweight. Of these, obesity and overweight were more in the 14 year age group of 1 (1.27%) and 4 (5.06%), respectively. Of the 272 boys of the urban school, 15 (21.91%) were obese and 38 (55.74%) were overweight. Of this, obesity was more among the 14-year-old children. Obesity in girls showed no statistical significance with the urban and rural population (P = 0.9, 64, 233).

Conclusions: Obesity is a serious health issue, resulting in both mortality and morbidity. We need to promote early intervention programs which should be aimed at weight reduction. Parents and children must be counseled not to eat junk foods and carbonated drinks.

Key words: Adolescent, Obese, Overweight, Prevalence

INTRODUCTION

Obesity is the most prevalent form of nutritional disorder in many of the affluent countries. Obesity is a state of excess adipose tissue mass. According to the WHO statistics, more than 1.6 billion people ≥15 year old are overweight or obese. As per various recent studies in India, 10-15% of school children are overweight. More than 66% of US adults are categorized as overweight or obese, and the prevalence of obesity is increasing rapidly in most of the industrialized world. Obesity is also associated with an increased risk of multiple health problems, including hypertension, Type 2 diabetes, dyslipidemia, obstructive sleep apnoea, non-alcoholic fatty liver disease, degenerative joint disease, and some malignancies; childhood obesity is not only confined to industrialized countries. Therefore, a rational clinical approach needs to be applied to preventing and treating this disorder.¹

Visceral adipose tissue is significantly related to concentrations of plasma low-density lipoprotein cholesterol and triglycerides in 11-15 year old as well as to concentrations of basal insulin and high-density lipoprotein cholesterol (inversely) in females aged 10-16 years.²

MATERIALS AND METHODS

The study was a cross-sectional, randomized, epidemiological study among adolescent school students of the rural and
urban school of a city in Kerala. A total number of 937 school children aged 12-15 years of both urban and rural school had participated in this study. Out of them, 445 were from the rural school, and 492 were from the urban school. The body weight was measured barefoot using a measuring scale and height to the nearest centimeter was taken. Body mass index (BMI) was calculated as weight (in kilograms) divided by height (in meter squared). For adolescent children, after BMI is calculated, the BMI number is plotted on the CDC BMI-for-age growth charts (4) (for either girls or boys) to obtain a percentile ranking. Percentiles are the most commonly used indicator to assess the size and growth patterns of individual children in the United States. Percentiles are used for adolescent because the amount of body fat differs between boys and girls and body fat also changes with age. The percentile indicates the relative position of the child's BMI number among adolescent children of the same sex and age. Healthy children have a BMI percentile ranging between 5th percentile and 85th percentile. The children whose weight were >85th to <95th percentile were considered as overweight and obese who were ≥95th percentile (WHO 2000).

Chi-square test was used to find out the significance. Odd’s ratio indicates that there is a strong hazardous association between sex and obesity.

RESULTS

Of the 254 girls of the rural school, 6 were Obese (8.74%) and 25 were overweight (42.66%). Of these, obesity and overweight were more common among 12-year-old girls, 6.06% and 12.12%, respectively (Table 1 and Figure 1).

Of the 220 girls of urban schools, 6 were obese (11.08%) and 21 were overweight (49.9%). Of these, obesity and overweight were more common in the 13 years old age group of 3 (5.56%) and 8 (14.29%), respectively (Table 2 and Figure 2).

Of the 191 boys of the rural school, only 1 (1.27%) was obese and 12 (29.13%) were overweight. Of these, obesity and overweight were more in the 14 year age group of 1 (1.27%) and 4 (5.06%), respectively (Table 3 and Figure 3).

Of the 272 boys of the urban school, 15 (21.91%) were obese and 38 (55.74%) were overweight. Of these, obesity was more among the 14-year-old children (Table 4 and Figure 4).

Obesity seems to be growing in children regardless of sex. In the USA, 16% of children and adolescent are obese and 20% are overweight. 4% of adolescents have sere obesity. It can be noted that there is a sex-wise variation in the prevalence of overweight and obesity in children irrespective of the place as revealed in many studies done.
The increase in weight and BMI over time has not been accompanied by an increase in height.

In adults, BMI is useful in the assessment of fatness. Concerns have been expressed regarding its use in children because it varies with height and does not take into account the differences in the timing of growth in height and weight among various ethnic groups. Nevertheless, it is easy to measure and has been validated against calculations of body density. For these reasons, it has been recommended by the American Society of Clinical Nutrition and others as a reliable measurement of overweight and obese children.

Obesity increases the likelihood of morbidity and mortality. Calle et al. prospectively examined the risk of death related to BMI in over a million adults and concluded that heavier men and women in all age groups had an increased risk of death. Must and Strauss reviewed the risks and consequences of obesity in childhood and adolescence and concluded that an aggressive approach to prevention and treatment was required. Treatment of obesity is most successful if realistic goals are set; a balanced diet is emphasized; a safe rate of weight loss of about 0.5 kg a week is achieved through moderate reduction of energy intake (about 20-25% decrease); increased physical activity

The rural and urban population of boys as well as girls were tabulated and significance values calculated. Obesity in girls showed no statistical significance with the urban and the rural population \( (P = 0.964233) \) Table 5. Boys showed a higher incidence of obesity in the urban setting as compared to the rural population \( (P = 0.000284) \) (Table 6).

**DISCUSSION**

We have found a highly significant increase in the number of overweight and obese children.
The delivery of programs through primary care has received a little formal assessment. Frequent contact with health professionals from an early age has been identified as an important strategy for effective management of obese children through the provision of advice, encouragement, and support for adopting healthy household eating and exercise patterns at an early stage in life. The incidence of childhood obesity is on the increase and obesity most likely will persist into adulthood. It results in considerable morbidity and mortality, especially due to cardiovascular disease. Physical activity, diet regulation in the form of reduction of high fat and high-calorie foods should be encouraged to reduce overweight and obesity.

**CONCLUSION**

The present findings indicate that prevalence of childhood obesity in Kerala - Ernakulam district is high. However, we found a higher frequency of obesity in boys as compared to the girls which are statistically significant. Obesity is a serious health issue, resulting in both mortality and morbidity. We need to promote early intervention programs which should be aimed at weight reduction. Parents and children must be counseled not to eat junk foods and carbonated drinks. School and college level health education and biannual screening may be of great help in this regard.
