Abstract

Introduction: Antenatal care (ANC) is the care of a woman throughout her pregnancy. The World Health Organization recommends a minimum of four antenatal visits comprising interventions such as tetanus toxoid (TT) vaccination, screening, and treatment of infections and identification of warning signs during pregnancy. The reasons for high maternal mortality ratio in India are inadequate access and underutilization of health services.

Materials and Methods: A cross-sectional study was conducted during May-June 2013 in the rural areas of Jawan, Aligarh. The study population comprised married women (15-49 years) who had delivery in the last 5 years. Informed consent was taken from each participant. A total of 100 mothers were selected for the study. Questionnaires were prepared for the study. Data were collected and analyzed using SPSS software.

Results: Majority of the mothers responded that pregnant women need to go for ANC checkup (95%). However, only 60% knew correctly the minimum number of ANC visits during pregnancy. 99% of mothers knew that TT should be given during pregnancy, but only 50% knew the correct dose. Although 84% of mothers knew the importance of iron folic acid (IFA) tablet, only 40% knew the correct dose. 85% of mothers knew about birth spacing, and 90% said it to be a good practice. 100% mothers knew that blood pressure should be recorded, but adverse effects of high blood pressure on fetus growth were reported only by 50% of females. More than half of mothers (56%) knew that emotional disturbances affected fetal growth. Most of the mothers knew the importance of blood and urine investigations.

Conclusion: Awareness should be developed in the community about the importance of registration for ANC, educating women about the detection of complications during pregnancy, importance of TT injection, IFA tablet, extra nutrition, etc. There is also the need to encourage women to involve their male partners in birth spacing programs. Health workers need to identify the pregnant mother, and they should give reminder before a particular dose of ANC.

Key words: Antenatal care, Knowledge, Mothers, Rural areas

INTRODUCTION

Antenatal care (ANC) is the care of a woman throughout her pregnancy. Almost 90% of maternal deaths occur in developing countries, and over half a million women die each year due to pregnancy and childbirth-related causes. Many women in developing countries do not receive such care. According to the National Family Health Survey, only about 50% of women received folic acid/iron supplements during pregnancy in India and this percentage is still lower in Rajasthan, Uttar Pradesh, Bihar, and Nagaland. The World Health Organization recommends a minimum of four antenatal visits comprising interventions such as tetanus toxoid (TT) vaccination, screening, and treatment of infections and identification of warning signs during pregnancy. In India, it is heartening to note that maternal mortality ratio (MMR) has declined from 212 in 2007-2009 to 178 in 2010-2012. The reasons for high MMR in India are inadequate access and underutilization of health services. Other common reasons are high illiteracy among females, early marriages, ignorance, malnutrition, social factors, etc. Hence, utilization of these services by...
the beneficiaries remains unsatisfactory.\textsuperscript{6-8} Two of the most important indicators of health of a country are life expectancy and maternal mortality rates.\textsuperscript{9} Nutrition during preconception as well as throughout pregnancy has a major impact on the outcome of pregnancy.\textsuperscript{10} Utilization of ANC is associated with the level of education and family income of the respondents.\textsuperscript{11}

The aim of this study was to assess the knowledge of mothers (15-49 years) regarding ANC services in rural areas of Aligarh.

**MATERIALS AND METHODS**

A cross-sectional study was conducted during May-June 2013 in the rural areas of Jawan, Aligarh. The study population comprised married women (15-49 years) who had delivery in the last 5 years. Informed consent was taken from each participant. A total of 100 mothers were selected for the study. Questionnaires were prepared for the study. Data were collected and analyzed using SPSS software. Full ANC is defined as at least 3 visits for ANC checkup, at least one TT injection received, and 100 iron folic acid (IFA) tablets/syrup consumed.\textsuperscript{12}

**RESULTS**

As shown in Table 1, majority of them responded that pregnant women need to go for ANC checkup (95%). However, only 60% knew correctly the minimum number of ANC visits during pregnancy. 99% of mothers knew that TT should be given during pregnancy, but only 50% knew the correct dose. Although 84% of mothers knew the importance of IFA tablet, only 40% knew the correct doses. 96% of mothers knew that smoking or alcohol intake is harmful to the fetus. 85% of mothers said that extra nutrition is necessary for pregnancy. 80% of mothers reported that deliveries should be conducted in institutions. 83% of mothers said that breastfeeding should be started within 24 h. 75% of mothers knew the importance of post-natal care.

As shown in Table 2, 85% of mothers knew about birth spacing and 90% said it to be a good practice. 95% had knowledge of one or other methods of birth spacing.

As shown in Table 3, 100% mothers knew that blood pressure should be recorded, but adverse effects of high blood pressure on fetus growth were reported only by 50% of females. 78% of mothers knew that ultrasonography was safe for fetus. More than half of mothers (56%) knew that emotional disturbances affected fetal growth. Most of the mothers knew the importance of blood and urine investigations.

**DISCUSSION**

As shown in Table 1, majority of them responded that pregnant women need to go for ANC checkup (95%). However, only 60% knew correctly the minimum number of ANC visits during pregnancy. This finding was similar to other study,\textsuperscript{13,14} in which the respondents had adequate knowledge about ANC registration, IFA tablet supplementation, TT injection, and increase in food intake, but knowledge regarding the number of ANC visits was dismal. The reason of good knowledge in our mothers was might be because of health education given to them by social workers of our center or Accredited Social Health Activists or Anganwadi workers in the villages. In our study, we do not correlate impact of mothers’ education on utilization of health services, but other studies found strong correlation between it.\textsuperscript{15,16}

Javali et al. study\textsuperscript{17} and Roy et al. study\textsuperscript{18} revealed 100% ANC registration.

ANC: Antenatal care, IFA: Iron folic acid, TT: Tetanus toxoid
A study reported results almost similar to our study, for example, 97.9% of mothers responded for ANC checkup although only 55.2% revealed the correct number of ANC visits. Similarly, 98.6% of mothers knew the importance of injection TT during pregnancy, but only 54.1% knew the correct number of times injection TT should be given.

In our study, 99% of mothers knew that TT should be given during pregnancy, but only 50% knew the correct dose. In another study also, pregnant mothers were aware of injection TT and IFA supplementation.

In our study, 80% of mothers said that deliveries should be conducted in institutions. An association between the use of ANC services and health facility delivery was observed in India and in other developing countries. Low level of knowledge of antenatal well-being and desire for hospital or assisted delivery was also observed in other studies.

The reasons for knowledge of ANC were might be because of close proximity and therefore easier accessibility of health facilities as stated by Magadi et al. that the frequency of ANC is also influenced by the accessibility of ANC service.

85% of mothers knew the importance of extra nutrition during pregnancy in our study. This is contrary to that revealed by Daba et al. where most of the respondents did not know the main food groups of the balanced diet and more than half did not know even the meaning of food. Despite the high level of respondents, some confusion and ignorance existed as regards maternal knowledge of adequate nutrition practices during pregnancy and identification of harmful food items in pregnancy.

As shown in Table 2, 85% of mothers knew about birth spacing and 90% said it to be a good practice. 95% had knowledge of one or other methods of birth spacing. These findings were similar to another study. The reasons of good information were because of good sources of health information such as health facilities, mass media, and family.

As shown in Table 3, 100% mothers knew that blood pressure should be recorded, but adverse effects of high blood pressure on fetus growth were reported only by 50% of females. Another study also reported that about half of the women did not know the complications that might arise among hypertensive and diabetic mothers.

**CONCLUSION**

Awareness should be developed in the community about the importance of registration for ANC, educating women about the detection of complications during pregnancy, importance of TT injection, IFA tablet, extra nutrition, etc. There is also the need to encourage women to involve their male partners in birth spacing programs. Health workers need to identify the pregnant mother, and they should give reminder before a particular dose of ANC.
