A Clinical Analysis of Eagle’s Syndrome by its Clinical Features and Therapeutic Response to Surgical Treatment

R T Abdul Salam
Associate Professor, Department of ENT, Government Medical College, Kozhikode, Kerala, India

Abstract

Background: Elongated styloid process is a relatively common disorder and is frequently misdiagnosed. Elongated styloid process with or without calcified stylohyoid ligament causes recurrent throat pain, foreign body sensation throat, dysphagia cervicofacial pain, and referred otalgia. Eagle’s syndrome is defined as the symptomatic elongation of the styloid process or mineralization (ossification or calcification) of the stylohyoid ligament complex. Diagnosis is based on history, production of symptoms on palpation of tonsillar fossa with a palpable styloid process, and relief of symptoms with injection of lignocaine into the tonsillar fossa. It is confirmed by radiology.

Aim of the study: The aim of this study is to evaluate the clinical, diagnostic, and therapeutic aspects of elongated styloid process.

Materials and Methods: A total of 42 patients with symptoms of elongated styloid process were included and confirmed by computed tomography (CT) scan and intraoral palpation method. All the patients were thoroughly investigated and the medical and surgical treatment efficacy was evaluated.

Observations and Results: Age of the 42 patients varied from 23 to 68 years. The mean age was 35.65 ± 3.10 years. The most commonly affected age group was 30–39 years. Of the total 42 patients, 18 were males and 24 were females.

Conclusions: Eagle’s syndrome is a relatively common disorder that is frequently misdiagnosed. Patients with vague cervicofacial pain, throat pain, foreign body sensation throat, referred otalgia, etc., should be palpated for elongated styloid process and investigated for the same. This condition has a female preponderance, and the most commonly affected age group is 30–39 years. CT scan styloid remains a radiological investigation to diagnose elongated styloid process with or without calcified stylohyoid ligament. Medical treatment will not give a long-standing symptomatic relief in elongated styloid process.

Key words: Eagle’s syndrome, Elongated styloid process, Stylalgia, Neuralgia

INTRODUCTION

Eagle’s syndrome was first documented by Eagle an otorhinolaryngologist.[1] Over a 20-year period, Eagle reported over 200 cases and explained that the normal styloid process is approximately 2.5–3.0 cm in length.[2] Due to his special interest in this syndrome, the condition has been named Eagle’s syndrome in his honor. Later, it has also been called as stylalgia, stylohyoid syndrome, styloid syndrome, “elongated styloid process syndrome,” “styloid process-carotid artery syndrome,” or “styloid process neuralgia.”[3] Eagle reported several cases of cervicopharyngeal symptoms associated with a radiographic diagnosis of an elongated, ossified styloid process occurring a few months post-tonsillectomy.[3] He described the symptoms as nagging or aching sensation in the throat, similar to chronic pharyngitis, and pain spreading to the ear and the mastoid region, difficulty in swallowing, and the sensation of a foreign object lodged in the throat.[4] It may develop inflammatory changes or impinge on the adjacent arteries or sensory nerve endings,
leading to the symptoms described. It had been estimated that between 2% and 4% of the general population presents radiographic evidence of an ossified portion of the stylohyoid chain.\textsuperscript{[9]} The majority of these patients are asymptomatic. The cartilaginous element of second arch (Reichert’s cartilage) gives rise to styloid process, stylohyoid ligament, lesser cornua, and probably the cranial rim of body of hyoid bone [Figure 1].

The clinical signs associated with a symptomatic styloid process were systematized by Eagle in a series of articles (1937, 1948, 1949, 1958).\textsuperscript{[1-3]} This syndrome was first documented by Eagle over a 20-year period. Loeser and Cardwell\textsuperscript{[6]} mentioned that the pain may also radiate to cheek, eyes, and forehead. They excised the tip of styloid process by an external approach with good results. Marchetti\textsuperscript{[7]} of Padua described a case of ossification in stylohyoid ligament. The length of the styloid process has been studied by Wang et al.,\textsuperscript{[8]} Thot et al.,\textsuperscript{[9]} Basekim et al.,\textsuperscript{[10]} and Jung et al.,\textsuperscript{[11]} from radiographs or three-dimension computed tomography (CT). Stylagia\textsuperscript{[12]} published a series of 52 cases, and according to him, the condition is more common than was generally thought. Christiansen et al.\textsuperscript{[13]} discussed in detail “styloid process neuralgia myth or fact,” and from their series, they believed that there was justification for the concepts that “elongated styloid process can produce pain” which is relieved by amputation of the tip. The length of styloid processes is variable. Kaufmann et al.\textsuperscript{[14]} reported that 30 mm is the upper limit for normal styloid process. Moffat et al.\textsuperscript{[15]} performed a cadaver study on styloid process and reported that the normal length is between 1.52 and 4.7 cm. Monsour and Young\textsuperscript{[16]} concluded that the diagnosis of elongated styloid process could be made whenever the styloid process was longer than 40 mm. Palpation of the styloid process in the neck superficial to the prominence produced by elongated styloid process will relieve the pain and patients reported temporary symptomatic relief. Radiological diagnosis remains the most definitive diagnostic criteria in elongated styloid process. In the literature, various radiological views have been discussed and analyzed by various authors. Brat\textsuperscript{[17]} suggested that transoral view is the best to detect this syndrome. Goldstein and Scopp\textsuperscript{[18]} in 1973 defined some diagnostic criteria based on panoramic X-rays. Three-dimensional (3D) CT is a valuable diagnostic imaging tool in patients with Eagle’s syndrome that allows clinicians to evaluate the styloid process in spatial geometry, make accurate length measurements, and explain the problem in detail to patients. For Arellano,\textsuperscript{[19]} Basekim et al.,\textsuperscript{[10]} and Heitz et al.,\textsuperscript{[21]} CT is the most effective method for evaluating the styloid process length and morphological alterations, since this examination provides two-dimensional and 3D reconstructions of the whole temporomandibular joint.

Type of Study
This was a prospective, cross-sectional, and analytical study.

Period of Study
The study duration was between June 2009 and October 20011.

Institute of Study
This study was conducted at Government Medical College, Kozhikode, Kerala.

MATERIALS AND METHODS
A total of 42 outpatients who presented with nagging throat pain, cervicofacial pain, foreign body sensation throat, and referred otalgia that were found to be having elongated styloid process with or without calcified stylohyoid ligament were included in this study. An ethical committee clearance certificate was obtained and a committee approved consent letter was used.

Inclusion Criteria
(1) Patients of all age groups were included. (2) Patients with confirmed elongated styloid process on CT scan were included. (3) Patients willing to undergo either surgery or medical treatment were included. (4) Patients with symptoms of throat pain, cervicofacial pain, foreign body sensation throat, and referred otalgia were included. (5) Patients with unilateral or bilateral symptoms were included.

Exclusion Criteria
(1) Patients with previous history of tonsillectomy were excluded. (2) Patients with diseases of the spine and
neuralgic pain in other parts of the body were excluded. (3) Patients with diabetes mellitus, hypertension, and malignant diseases of the oral or pharyngeal cavity were excluded. A thorough clinical history was taken. Various radiological views for styloid process are compared to select a diagnostic tool. Various medical and surgical treatments with the incidence of complications are also analyzed in the present study. All the patients in the study group underwent clinical examination palpation of tonsillar fossa. Apart from routine blood, urine, blood sugar, and renal function tests, radiological investigations were also done to diagnose elongated styloid process. Radiological evaluation of cervical spine and barium swallow studies were done in selected patients to rule out cervical spine disorders and pharyngoesophageal causes, respectively (Figure 5). All the data were analyzed using standard statistical methods.

**Medical Treatment**

Of 42 patients diagnosed, 16 patients were not willing for surgery. Hence, medical treatment was tried in these patients with temporary and variable results. Temporary symptomatic relief was obtained in 14 patients with carbamazepine 100–200 mg once/twice daily, amitriptyline 10–50 mg once/twice daily, and weeks to month’s diclofenac sodium 50 mg twice/thrice daily for a short course.

**Surgical Treatment**

Surgical treatment of elongated styloid process was the main mode of treatment. Bilateral excision was done in 19 patients and unilateral excision in 7 patients. In all these patients, styloid process was palpable per orally. CT scan showed elongated styloid process. Surgery was done under general anesthesia using nasotracheal intubation except in 3 patients where nasotracheal intubation was difficult. Hence, orotracheal intubation was done. Patient was placed in Rose’s position as in tonsillectomy. Mouth was kept open using Boyle–Davis mouth gag, and tonsillectomy was done by classical dissection and snare method. Superior constrictor was separated at the point where the styloid process was prominent and palpable. The tip of styloid process was then delivered. The periosteum was incised at the tip, elevated, and reflected back. The styloid process was broken and removed with a bone nibbler or Luc’s forceps [Figure 2]. After excision, the superior constrictor muscle was closed with catgut sutures and bleeding points were ligated if any. Postoperatively, oral feeding in the form of cold liquid was started after 6 h as in tonsillectomy. Parenteral antibiotics in the form of ampicillin and gentamicin were given for 2 days. Patients were discharged after 2 days with oral antibiotics and followed up for 1 year at 1 week, 3 weeks, 2 months 6 months, and 1 year.

**OBSERVATIONS AND RESULTS**

**Age and Sex Distribution**

Age of the patients varied from 23 to 68 years. The mean age was 35.65 ± 3.10 years. The most commonly affected age group was 30–39 years. Of the total 42 patients, 18 were males and 24 were females. The most commonly affected are middle-aged females. The age and sex distribution is presented in Table 1 and Charts 1-3.

**Side Affected**

By symptomatology, the condition was unilateral in 36 patients and bilateral only in 6 patients. Intraoral palpation detected palpable styloid process affected side in 30 patients and both sides 12 patients.

**Chart 1: Age and sex distribution**

**Chart 2: Sex incidence**
**Symptomatology**

Majority of patients reported vague and multiple symptoms and the most common symptom was needle pricking sensation on the affected side of the throat.

71.4 patients complained needle pricking sensation on the affected side of the throat. 61.9% of the study group showed foreign body sensation throat on the affected side, and 47.6% complained of aggravating of the symptoms on swallowing and referred pain in the ipsilateral ear. Pain in the temporomandibular area was reported by 28.6%. Other symptoms include pain on changing the head posture 9.5% and headache 14.3%. In 14.3% of the study group, the symptoms were bilateral. Radiation of pain to the surrounding area was complained by 80.95% Table 2.

**Intraoral Palpation**

On intraoral palpation, 71.4% were unilateral and 28.6% were bilateral. In all patients, same symptoms were reproduced on intraoral palpation of the elongated styloid process. Elongated styloid process was graded according to the tip of styloid process to the tonsillar fossa. In 4 patients (14.3%), the tip of styloid process was palpable in the upper pole of tonsillar fossa (Grade 1) on the affected side. In 23 patients, the tip was palpable in the middle of tonsillar fossa (Grade 2), and in 15 patients, the tip was palpable in the lower pole of the tonsillar fossa (Grade 3). Among these, two patients had the tip projecting to the tongue base.

**CT Scan**

We compared the commonly used radiological studies such as X-ray lateral view of head and neck for styloid, x-ray skull AP view with open mouth, and orthopantomogram with CT styloid. It was found that CT scan is a very useful diagnostic tool. Unilateral elongated styloid process was visualized in 10 patients (23.8%) and bilateral in 32 patients (76.2%). Of the total 42 patients, 18 patients (43%) had calcified stylohyoid ligament [Figures 3 and 4]. In unilateral cases, calcified stylohyoid ligament was seen in 2 patients, and in bilateral cases, calcified stylohyoid ligament was seen in 16 patients. For calcified stylohyoid ligament, there was no sex predilection. Majority of patients (89%) with calcified stylohyoid ligament were above 40 years.

**Treatment**

Of 42 patients diagnosed, 26 patients underwent intraoral excision of elongated styloid process under general anesthesia. 16 patients were not willing for the surgery and these patients were treated with drugs such as carbamazepine, amitriptyline, and diclofenac sodium. Bilateral excision was done in 19 patients and unilateral excision in 7 patients.

**Complications**

Four patients had diffuse swelling behind the angle of mandible extending to submandibular region noticed on the 2nd post-operative day which subsided by itself by the end of 1st week. 1 patient was readmitted with features of parapharyngeal cellulitis 1 week after the surgery, and she was treated with parental antibiotics and other supportive measures.

**Follow-up**

Patients were followed up at intervals of 1 week, 3 weeks, 2 months, 6 months, and 1 year to know the recurrence or persistence of the symptoms after surgery. On follow-up, 3 patients complained of persistent foreign body sensation throat and they were put on amitriptyline with the improvement of symptoms.

**DISCUSSION**

Patients who attended ear, nose, and throat (ENT) outpatient department at medical college hospital, Calicut, between June 2009 and October 2011, with nagging throat pain, cervicofacial pain, and foreign body sensation throat were analyzed. Of these, 42 patients were found to be having elongated styloid process. In this study, clinical, diagnostic, and therapeutic parameters of elongated styloid process are discussed.
Age and Sex Characteristics

In this study, the youngest patient was 23-year-old and the oldest was 68-year-old. Majority of these were in the 30–39 years age group. Age incidence in our study is compared with some of the major studies in the available literature [Table 3].

According to Stylagia,\(^{[12]}\) 20–29 years was the most commonly affected age group. Verma\(^{[23]}\) (1995) reported a maximum number of patients in 30–39 and 40–49 years age group. Our study shows a maximum number of patients in 30–39 years of age group and this was also observed by Verma.\(^{[23]}\) The female predominance is noted in all major studies in the literature [Table 4], i.e., Strauss et al.\(^{[24]}\) 87.5%, Verma\(^{[23]}\) (1995) 85.5%, Moffat et al.\(^{[19]}\) 75%, and Stylagia\(^{[12]}\) 61.6%. The present study also shows a female preponderance of 57.14% [Table 4].

Side Affected

In the literature, bilateral symptoms were noticed by Stylagia\(^{[12]}\) in 25% and Verma\(^{[23]}\) (1995) in 67.3%. Moffat et al. and Christiansen et al.\(^{[13]}\) have reported bilateral symptom in none of their series. The present study only 14.28% of the study group has bilateral symptoms, but CT showed 85.71% had bilateral elongated styloid process [Table 5].

Symptomatology

Elongated styloid process is notorious for its diverse symptomatology. All the literatures available have confirmed this diversity. In the present study, the most common symptom was needle pricking sensation on the affected side of the throat (71.4%). The next most common symptoms were foreign body sensation throat on the affected side (61.9%), pain on swallowing, and referred otalgia (47.6%). Verma\(^{[23]}\) in 1996 reported pain on swallowing and throat pain as predominant symptoms. Authors like Stylagia\(^{[12]}\) and Strauss et al.\(^{[24]}\) reported cervical pain as the most common symptom. According to Bhide,\(^{[22]}\) referred otalgia was the predominant symptom. In this study, the other symptoms noticed were pain on the side

![Figure 2: Intraoral palpation](image1)

![Figure 3: The styloid process at surgery](image2)

![Figure 4: The computed tomography scan three-dimensional picture with elongated styloid process](image3)

![Figure 5: X-Ray of the neck showing schematic representation of the styloid process](image4)
of neck (33.3%), pain in the temporomandibular joint area (28.6%), and pain on changing the head posture (9.5%). A small number of patients also reported other symptom like headache.

**Clinical Examination**

Apart from other routine general and ENT examination, palpation of the tonsillar fossa for elongated styloid process was a very useful diagnostic method. According to Verma, elongated styloid process was graded according to the relation of the tip of the styloid process and the tonsillar fossa.

1. Grade I: The tip of the styloid process palpable in the upper pole.
2. Grade II: The tip of the styloid process palpable in the middle of the tonsillar fossa.
3. Grade III: The tip of the styloid process palpable in the lower pole and tongue base.

In our study group:
- 4 patients - Grade I
- 23 patients - Grade II
- 15 patients - Grade III

Palpation of the tip of the styloid process in the tonsillar fossa produced aggravation of characteristic symptoms in all these patients.

**Radiological Study**

Even though the radiological study remains the most helpful diagnostic method in Eagle’s syndrome, a single definite radiological view is still not advocated in available literature. Various authors have suggested different radiological views [Table 6].

Orthopantomogram is considered as a very useful view by many authors like Goldstein and Scopp, Baddour, and Carmada et al. Exaggerated Towne’s view was suggested by Lavine et al. in 1968. In our study, we compared lateral view of head and neck, lateral oblique view, posteroanterior view of skull, orthopantomogram, and CT styloid in a few of our patients. It was found that CT styloid was very useful diagnostic tool and was taken in all our patients. In the study, the longest styloid process measured radiologically by CT was 6.2 cm. CT scan styloid process: In this study, unilateral elongated styloid process was found in 10 patients (23.8%) and bilateral in 32 patients (76.2%). Of the total 42 patients, 18 patients (43%) had calcified stylohyoid ligament. In unilateral cases, calcified stylohyoid ligament was seen in 2 patients (20%), and in bilateral cases, bilateral calcified stylohyoid ligaments were seen in 16 patients (50%). For calcified styloid ligament, there was no sex predilection. Majority of patients (89%) with calcified stylohyoid ligament was above 40 years and increased predilection for calcification of stylohyoid ligament was seen in cases with bilateral elongated styloid process. On comparing the signs and symptoms of patients with elongated styloid process with calcified stylohyoid ligament and elongated styloid process without stylohyoid ligament, it is seen that there is no difference in the symptoms in these two groups. Hence, stylohyoid ligament calcification perse associated with elongated styloid process is not producing any additional symptoms when compared with isolated elongated styloid process without stylohyoid ligament calcification. In this study, we recommend CT scan styloid process as the effective radiological investigation to diagnose elongated styloid process with or without calcified stylohyoid ligament. Diagnostic role of CT scan in Eagle’s syndrome was stressed by Baddour and Carmada et al. Treatment: Conservative treatment: In the study group of 42 patients, 16 patients (42.9%) were not willing for surgery. In these patients, medical treatment

</table>
was given with carbamazepine 100–200 mg once/twice daily, amitriptiline 10–50 mg once/twice daily weeks to months, and diclofenac sodium 50 mg twice/thrice daily for a short course. Most of the patients reported temporary symptomatic relief. Bhide\[^{[23]}\] also reported temporary relief in most of the patients studied with carbamazepine. Injection of 2% lignocaine in the tonsillar fossa also offered some temporary symptomatic relief in most of the patients studied. Steinmann in 1970 described the use of long-acting local anesthetic and steroid solution for conservative management of Eagle's syndrome. Surgical treatment: 26 patients (57.1%) in the study group were subjected to intraoral excision of elongated styloid process under general anesthesia. Most of the authors in the literature also advocate intraoral approach (Eagle 1958, Murthy et al\[^{[31]}\] etc.). This is a safe, simple, and more familiar approach to all ENT surgeons with no neck incision and very minimal complications. Intraoral excision does not involve greater morbidity than a routine tonsillectomy. External approach requires a neck incision, and in rare occasions, there is a chance for facial nerve palsy also. Among 26 patients operated, bilateral excision was done in 19 patients (73%) and unilateral excision was done in 7 patients (26.92%). Complications: In 4 patients (9.52%), a diffuse swelling behind the angle of the mandible extending to the submandibular area was observed on 2nd post-operative day which subsided by itself by the end of 1st post-operative day. Eagle in 1958 reported this complication in 25 patients of 150 total patients (16.7%). Submandibular swelling was also noticed by Murthy et al.\[^{[10]}\] in 10% and by Strauss et al.\[^{[27]}\] in 25% of their patients [Table 7].

In this study, 1 patient (2.4%) was readmitted with features of parapharyngeal cellulitis 1 week after the surgery and she was treated with parenteral antibiotics and other supportive measures. Even though infection of deep neck space is a well-documented complication of intraoral approach, this is a rarely reported complication in the literature. Eagle\[^{[11]}\] did not report even a single patient with this complication in his large series of 150 patients. Follow-up: Patients were followed up for 1 year at 1 week, 3 weeks, 2 months, 6 months, and 1 year. 3 of our patients (7.1%) complained persistent symptoms in the form of foreign body sensation throat after surgery, and they were treated with amitriptiline with improvement of symptoms.

**CONCLUSIONS**

Eagle’s syndrome is a relatively common disorder that is frequently misdiagnosed. Patients with vague cervicofacial pain, throat pain, foreign body sensation throat, referred otalgia, etc., should be palpated for elongated styloid process and investigated for the same. This condition has a female preponderance and the most commonly affected age group is 30–39 years. CT scan styloid remains a radiological investigation to diagnose elongated styloid process with or without calcified stylohyoid ligament. Medical treatment will not give a long-standing symptomatic relief in elongated styloid process. Intraoral excision of the elongated styloid process is the treatment of choice of this condition. This is a safe and easy procedure, which does not involve greater morbidity than a routine tonsillectomy, and is familiar to all ENT surgeons.
