Abstract

Background: The purpose of this study was to assess the photocatalytic titanium oxide surface modified stainless steel and nickel–titanium (NiTi) wires for its antiadherent and antibacterial properties against Streptococcus mutans.

Materials and Methods: The study was preceded on 80 specimens of stainless steel and NiTi wires which were divided into four groups each having two subgroups. Groups containing uncoated wires acted as control groups for their respective experimental groups containing coated wires. Surface modification of wires was performed with TiO₂ sol which was further heated at 400°C. For assessment of antiadherent and antibacterial properties of wires, microbiological test against S. mutans was performed.

Result: Orthodontic wires coated with TiO₂ showed antiadherent effect against S. mutans as compared to uncoated wires. The groups containing surface modified wires showed a statistically significant decrease in the survival rate of S. mutans expressed in the colony-forming unit when compared to the groups containing uncoated wires.

Conclusion: Surface modification of the orthodontic wires can be used to prevent accumulation of dental plaque, hence, the development of periodontal problems as well as dental caries during fixed orthodontic treatment.

Key words: Antiadherent properties, Antibacterial properties, Nickel-titanium wires, Stainless steel wires, Streptococcus mutans, TiO₂

INTRODUCTION

Fixed orthodontic appliances are the most common habitat for dental caries and periodontal diseases. Although there are many reasons which may cause dental caries and periodontal diseases such as physical, chemical, and biological characteristics of dental plaque, the oral environment with fixed appliances provides ideal conditions for colonization of microorganisms as a result of their inherent morphological irregularities.¹

The incidence of enamel demineralization and periodontal diseases after fixed orthodontic treatment can involve up to 50% of the patients.²

Among different components of fixed orthodontic appliances, wires are present throughout the course of orthodontic therapy and hence pay a crucial part in causing demineralization of enamel surface.

The wire bracket interface provides unique conditions that hinder proper access to the tooth surface for cleaning,
**MATERIALS AND METHODS**

The study was done on 80 specimens of 0.016" stainless steel and NiTi wires of 4 cm length. The specimens were divided into four groups and further divided into two subgroups of each group have a control and experimental group, in which the control group consisted of uncoated wires and the experimental group consisted of photocatalytic TiO₂ coated wires. Group 1 and 3 consisted of stainless steel wires and Group 2 and 4 consisted of NiTi wires (Table 1). All the groups were then assessed for antiadherent and antibacterial properties.

**Bacterial Strains**

*S. mutans* was used for the antiadherent and antibacterial tests. *S. mutans* was inoculated overnight in 5 ml of brain heart infusion (BHI) for adhesion test, 10% of the broth after 24 h of inoculation was transferred to 10 ml of BHI broth which contained 10% sucrose, which was further incubated for 24 h.

**Coating of Stainless Steel and NiTi Wires with Photocatalytic TiO₂**

Coating of stainless steel and NiTi wires with photocatalytic TiO₂ was done by sol-gel method. In this method, 0.40 g of titanium isopropoxide was dehydrolized in deionized aqueous solution. As a result, titanium hydroxide as a precipitate was achieved, which was separated by decantation process. The precipitate was further washed thoroughly with water until the alcohol generated during the hydrolysis was completely removed. The precipitate was then dissolved in 10 ml of hydrogen peroxide, which gave the yellowish orange solution of titanium peroxy complex. Thus, the TiO₂ sol was prepared (Figure 1).

The wires were cleaned, air dried, then dipped in solution for 5 min, and then were pulled out with motor-operated equipment in uniform motion. Wires were then dried at room temperature. Further, the coated wires were heated for 5 h under electric furnace at 400°C (Figure 2).

**Figure 1: Prepared TiO₂ sol**
Assessment of Bacterial Adhesion to Orthodontic Wires

Before adhesion test, adventitious macroscopic contaminations of the wire were removed by ultrasonication in 2-propanol for 5 min and were dried in a desiccator. After that, the wires were sterilized in an autoclave and were pre-weighed on analytical balance and were stored in container having 10 ml of BHI broth (Figure 3). An overnight cultured *S. mutans* growth was inoculated to final concentration of 10% and was incubated for 24 h at 37°C under illumination of ultraviolet (UV)-A black light inside the incubator (Figure 4). Wires were carefully removed and then immersed in 10% formaldehyde solution for 30 min to immobilize the cells. The wires were then weighed under analytical balance for bacterial adherence.

Assessment of Antibacterial Properties of Orthodontic Wires

The antibacterial properties of orthodontic wires were demonstrated against *S. mutans*. The culture media used were BHI agar, and the disc diffusion method was carried out. BHI agar plates were brought at room temperature, and the inoculum preparation was done using a swab to transfer the colonies onto the plates. Turbidity was adjusted visually with broth to equal that of 0.5 McFarland turbidity standard. The suspension was standardized with a photometric device. After that, the inoculation of other plates was done in 15 min by adjusting the inoculum to McFarland turbidity standards; a sterile cotton swab was dipped against the walls of the tube above the liquid to remove the excess inoculum. After that, the wires were placed in the plate, and the plates were illuminated with a UV-A black light inside the laminar air flow chamber with an intensity of 1.0 MW/cm² for 60 min (Figure 5). Antibacterial activity was described as the survival rate for colony-forming units (CFUs) for *S. mutans*.

Table 1: Groups of coated and uncoated wires used for antiadherent and antibacterial activities

| Group 1 | Group 1a | Control group – Consisted of 10 uncoated stainless steel wires that was used for evaluation of bacterial adhesion to orthodontic wires
| Group 1b | Experimental group – Consisted of 10 surface modified stainless steel wires with photocatalytic TiO₂ thin film which was used for evaluation of bacterial adhesion to the orthodontic wires
| Group 2 | Group 2a | Control group – Consisted of 10 uncoated NiTi wires that used for the bacterial adhesion
| Group 2b | Experimental group – Consisted of 10 surface modified NiTi wires with photocatalytic TiO₂ thin film which was used for bacterial adhesion
| Group 3 | Group 3a | Control group – Consisted of 10 uncoated stainless steel wires used for evaluation of antibacterial property
| Group 3b | Experimental group – Consisted of 10 surface modified stainless steel wires with photocatalytic TiO₂ thin film which was used for evaluation of antibacterial property to the orthodontic wires
| Group 4 | Group 4a | Control group – Consisted of 10 uncoated NiTi wires that was used for the antibacterial property
| Group 4b | Experimental group – Consisted of 10 surface modified NiTi wires with photocatalytic TiO₂ thin film which was used for antibacterial property

Statistical Analysis

The results were evaluated by SPSS 12.0 K software (SPSS Inc., Chicago, IL, USA). A paired *t*-test was used for the
bacterial adhesion test, and Kruskal–Wallis H-test was applied for the antibacterial activity tests.

RESULTS

Adhesion of S. mutans on the Surface of Orthodontic Wires

From the data shown in Table 2, it is observed that there was a significant increase in the weight of the uncoated wires of Group 1b and 2b and coated wires of Group 1a and 2a showed less change in weight than the uncoated wires and hence, showing the antiadherent property of coated wires.

Antibacterial Activity of Surface Modified Orthodontic Wires on S. mutans

The survival rate of bacterial cells was calculated in terms of CFU as shown in Table 3, Group 3a and 4a having uncoated wires showed a significant increase in bacterial colony when compared to Group 3b and 4b which contained the surface modified wires showing a statistically significant decrease in bacterial colony.

DISCUSSION

The present study was undertaken to modify the surface of stainless steel and NiTi wires with photocatalytic TiO$_2$ and to assess their antiadherent and antibacterial properties against S. mutans. It is possible that a sufficient amount of reactive oxygen species such as OH was released from the TiO$_2$ coated wires as a result of UV-A light, whereas reduced adhesion of S. mutans to the TiO$_2$ coated wires might be a result of decomposition of surface organic molecules of S. mutans such as M protein. This phenomenon might further cause the cell walls of bacteria to become more fragile.

The photocatalytic activity of illuminated TiO$_2$ has been actively investigated in adverse areas such as water treatment processes, air cleaning agents, and antibacterial agents. TiO$_2$ might be sufficient to degrade the microbial cell components which are mainly composed of organic compounds.

Among the various infectious organisms in the oral cavity, S. mutans is one of the most closely investigated organisms in dentistry to cause enamel decalcification and periodontal diseases.

The main problem faced by orthodontists during fixed orthodontic treatment is the development of dental plaque, which is initiated by the adhesion of S. mutans to the tooth surface on the fixed orthodontic appliance.

Several studies have been conducted for the antibacterial properties of TiO$_2$.

Zhang et al. in their study concluded that because of TiO$_2$ there is disintegration of bacterial cell wall. Jacob et al. also proved that organic matters in the cell can be decomposed completely by photocatalysis of TiO$_2$. Caballero composited the TiO$_2$ photocatalyst into acrylic paint, and this coating could kill Escherichia coli.

Various studies have also been conducted for the antiadherent property of TiO$_2$. Shi et al. excogitated a

*Statistically significant
self-cleaning coating and said that dust on the wall will be abscised together with TiO$_2$. Qin prepared TiO$_2$/Al by liquid phase deposition and then blended it with coating. The self-cleaning performance was evaluated in the end. Oleic acid was the pollution stimulant.\(^1\)

Shah et al. found the photocatalytic TiO$_2$ surface modified stainless steel bracket has an antiadherent and antibacterial property against Lactobacillus acidophilus.\(^1\) Mhaske et al. found the same result with the stainless steel and NiTi wires against Lactobacillus acidophilus.\(^2\) Study done by Chattani et al. on photocatalytic TiO$_2$ coated NiTi and stainless steel wires demonstrated antiadherent and antibacterial property against S. mutans.\(^3\)

In this study, surface modified NiTi and SS wires with photocatalytic TiO$_2$ showed effective antiadherent and antibacterial property against S. mutans.

**CONCLUSION**

- Photocatalytic TiO$_2$ coating on SS and NiTi wire prevented the adhesion of S. mutans, hence demonstrating antiadherent property.
- The photocatalytic TiO$_2$ also revealed antibacterial effects against S. mutans.
- Surface modification of orthodontic wires with photocatalytic TiO$_2$ can be used to prevent the development of dental plaque and dental caries during orthodontic treatment.
