Abstract
Objective: To assess oral hygiene behavior among patients undergoing fixed orthodontic treatment.

Material and Method: One hundred orthodontic patients (37 males and 63 females) undergoing fixed orthodontic treatment in the Department of Orthodontics Indira Gandhi Government Dental College, Jammu were studied. Patients were asked to fill the provided questionnaire regarding the reason for opting orthodontic treatment, oral hygiene behavior after placement of fixed orthodontic appliances. The result was statistically analyzed using SPSS software version 20 for interpretation of data.

Results: Most of the patients used orthodontic toothbrush and fluoridated toothpastes to maintain oral hygiene but frequency of brushing for majority of the subjects was only once. Majority of the females used interdental brush and floss (57.14% and 33.33% respectively) regularly whereas majority of the males (78.37%) used mouthwash as a supplemental oral hygiene aid. There was no statistically significant gender difference with the selection of oral hygiene products.

Conclusion: Patients undergoing fixed orthodontic treatment are required to be educated and motivated to maintain their oral health. Orthodontists should emphasize on increasing the awareness of the patients towards maintaining oral hygiene with various oral hygiene measures to prevent dental caries and periodontal disease during fixed orthodontic treatment.

Key words: Fixed Orthodontic treatment, Oral hygiene behavior, Orthodontics, Jammu

INTRODUCTION

Patient undergoes orthodontic treatment to enhance esthetics, function, and increase self esteem. However, fixed orthodontic therapy is often associated with various risk factors like white spot lesions (enamel demineralization), tooth decay, marginal gingivitis, gingival enlargement. Studies done in the past have shown that orthodontic therapy can lead to respective risk factors. Excessive plaque retention adjacent to brackets and attachments is the cause of this white spot lesion. One of the major and most common challenges in prevention within the field of oral health is the control of plaque and, consequently, the control of dental caries and gingival inflammation. Fixed orthodontic appliances with bands, coils, elastics, orthodontic archwires, and direct bonding of brackets influence the accumulation of dental plaque.

Various studies evaluated and compared the effectiveness of various plaque elimination methods like manual or electric toothbrushes on plaque elimination for patients undergoing orthodontic treatment, whereas some of them evaluated the efficiency of toothpastes and mouthwashes with different ingredients, on gingival health and plaque elimination.

Hence, it is a challenge for the orthodontist to maintain proper oral hygiene in patients undergoing fixed orthodontic
treatment to prevent various risk factors associated with the accumulation of dental plaque. Thus the purpose of the present study is assessment of oral hygiene behavior among patients undergoing fixed orthodontic treatment.

MATERIALS AND METHOD

One hundred orthodontic patients (37 males and 63 females) undergoing fixed orthodontic treatment in the Department of Orthodontics Indira Gandhi Government Dental College, Jammu were studied. Patients were asked to fill the provided questionnaire regarding the reason for opting orthodontic treatment, oral hygiene behavior after placement of fixed orthodontic appliances. The result was statistically analyzed using SPSS software version 20 for interpretation of data. The questions regarding the selection of toothbrush, toothpaste and supplemental oral hygiene products, frequency of brushing and oral hygiene education, as received from orthodontist.

RESULTS

The results of our study showed that out of total 100 subjects undergoing fixed orthodontic treatment majority of the males and females (54.05% and 55.5% respectively) chose orthodontic toothbrush to maintain oral hygiene, followed by 21.6% males and 23.8% females choosing ultrasoft toothbrush (Table 1). The results of our study showed that 45.94% males and 52.38% females used to brush once a day followed by 32.43% males and 30.15% females who used to brush twice a day. A lesser percentage of 21.6% and 17.46% of males and females used to brush after every meal (Table 2). Table 3 shows that 78.4% of males and 74.6% females used fluoridated toothpaste in comparison with 21.6% males and 25.4% females who used non-fluoridated toothpastes. Table 4 shows that during orthodontic treatment, majority of the females i.e. 57.14 % used interdental brush regularly whereas 37.8% of males use interdental brush occasionally.

DISCUSSION

Orthodontic treatment helps to improve the patient’s self esteem, facial aesthetics and masticatory functions. [17,18] Inspite of various advantages of fixed orthodontic appliances they were found to contribute towards increased plaque accumulation and if proper oral hygiene measures were not implemented it will lead to gingivitis, dental caries, and halitosis. [19,20]

In the present study, majority of the males and females used orthodontic toothbrush, which is in accordance with the findings of study done by Anuwongnukroh N et al. [21] However certain studies showed conflicting results regarding the effectiveness of the orthodontic toothbrush in reducing plaque when compared with conventional toothbrush. [22,23]

The results of our study showed that majority of the males and females brush only once a day which is contradictory with the findings of Anuwongnukroh N et al. [21] who found that majority of the subjects (44.8%) brushed their teeth twice a day, while the remaining brushed more than twice. Our study showed that majority of the subjects used fluoridated tooth pastes which is in agreement with other studies like 82% of the patients in one of the study used fluoridated toothpaste, whereas 6.7% of the samples did not use fluoridated toothpaste. [21] The results of the present study showed that majority of the females used interdental brush and dental floss regularly as a supplemental oral hygiene aid whereas males used mouth wash more in comparison to other supplemental oral hygiene products. [24-28]

The studies done with the use of oral irrigator are very sparse and further studies are required to prove its efficacy. As fixed orthodontic treatment reduces the efficiency of the patient to maintain oral hygiene, it is important for the orthodontist to give proper education regarding the use of oral hygiene aids and maintain the oral hygiene properly.
